

Product Cost Calculator (Excel)

A free Excel template for calculating the cost of a product made from multiple ingredients—whether it's recipes, beverages, handmade goods, or anything else you create from raw materials and want to accurately value in monetary terms.

P.S. Unfortunately, this version doesn't automatically factor in packaging or other associated costs. However, if even a few people see and use this project, I'll work on adding those features. Enjoy using it!

It is suitable for small-scale producers, home bakers and baristas, and anyone who sells handmade goods and wants a quick, consistent way to answer the question: "What does it actually cost me to make this?"

Read in Russian

How it works

The file contains two sheets:

1. settings — the ingredient database

Enter each ingredient here once: the price paid and the quantity received. The sheet automatically calculates the price per gram/ml and per 100g/ml, allowing you to use each ingredient in any recipe.

Product	price(per 1 pac)	quantity(g)	price (per 1ml/g)	price (per 100g/ml)	Link on product
Coffee	\$ 5.00	100	\$ 0.05	\$ 5.00	link
Milk	\$ 10.00	20	\$ 0.50	\$ 50.00	link
Sugar	\$ 3.00	30	\$ 0.10	\$ 10.00	link
Syrop	\$ 5.00	10	\$ 0.50	\$ 50.00	link
Cup	\$ 5.00	6	\$ 0.83	\$ 83.33	link

Fill in the gray- shaded cells yourself (product name, price per package, quantity, product link).

The unshaded columns are calculated automatically; do not edit them.

2. Calculation — recipe blocks

The sheet consists of a grid of identical blocks (55 in total)—one block for each product whose cost price needs to be calculated.

Product name	Cappuccino		portion	1
#	Grocery	Quantity	price	
1	Coffee		\$ 0.6000	
2	Sugar		\$ 0.2000	
3	Milk		\$ 1.1000	
4	Syrup		\$ 0.1500	
5			\$ -	
6			\$ -	
7			\$ -	
8			\$ -	
9			\$ -	
10			\$ -	
11			\$ -	
12			\$ -	
13			\$ -	
14			\$ -	
15			\$ -	
			depreciation(%)	20%
			Work(%)	70%
			Work + deprec.	\$ 1.8450
			Total Price	\$ 3.8950
			Price per 1	\$ 3.8950

Enter the product name and the number of units (portions) yielded from the batch.

For each ingredient, select it from the "Grocery" drop-down list (populated directly from the "Settings" sheet) and enter the "Quantity" used; the "Price" column will fill in automatically.

Set the depreciation % and work %—your markup for equipment wear and tear and labor, calculated as a percentage of the raw material cost.

"Total Price" and "Price per 1" (unit price) are calculated automatically.

How to get started:

Download the .xlsx file and open it in Excel, LibreOffice Calc, or Google Sheets.

Enter your ingredients on the "Settings" sheet.

Select an empty block on the "Calculation" sheet, name the product, and start adding ingredients. Repeat for as many products as needed—the template is set up for 55 out of the box, while the ingredient database supports up to 500 items.

Notes:

All formulas are in English (VLOOKUP, IFERROR, IF), regardless of your Excel interface language—they work the same way for everyone.

This is a personal side project shared "as-is"—in case it proves useful to others. I welcome feedback and suggestions—please submit them via the "Issues" section. The product is open and available to everyone.
